- PHP and MySQL

# Class

# Object oriented programming in PHP

- PHP, like most modern programming languages (C++, Java, JavaScript, etc.), supports the creation of objects.
- Creating an object requires you to first define an object class (containing variables and/or function definitions) and then using the "new" keyword to create an instance of the object class. (Note that the object must be defined before you instantiate it.)

## Defining (declaring) a class

 Use the "class" keyword which includes the class name (case-insensitive, but otherwise following the rules for PHP identifiers). <u>Note</u>: The name "stdClass" is reserved for use by the PHP interpreter.

```
<?php
class Person
{
    public $name;
    function set_name($new_name) {
        $this -> name = $new_name;
    }
    function get_name() {
        return $this -> name;
    }
}
```

 Use the "\$this" keyword when accessing properties and functions of the current object

# Declaring a class (cont.)

- Properties and functions can be declared as "public", "private", "protected"
- Default access: public

```
<?php
class Person
{
   protected $name;
   protected $age;
   function set_name($new_name) {
        $this -> name = $new_name;
   }
   function get_name() {
       return $this -> name;
   }
}
```

### Accessing properties and methods

 Once you have an object, you access methods and properties (variables) of the object using the -> notation.

```
<?php
$me = new Person();
$me -> set_name('Russ');
$name = $me -> get_name();
echo $me -> get_name();
$age = 36;
$me -> set_age($age);
?>
```

#### Constructors and destructors

- Constructors are methods that are (generally) used to initialize the object's properties with values as the object is created.
- Declare a constructor function in an object by writing a function with the two underscores "

```
<?php
class Person {
   protected $name;
   protected $age;
   function __construct($new_name, $new_age) {
        $this -> name = $new_name;
        $this -> age = $new_age;
   }
   // . . . other functions here . . .
}
$p = new Person('Bob Jones', 45);
$q = new Person('Hamilton Lincoln', 67);
```

Destructors (defined with a function name of \_\_destructor() ) are called when an object is destroyed

#### Inheritance

Use the "extends" keyword in the class definition to define a new class that inherits from another.

```
<?php
 class Employee extends Person {
    public $salary;
     function construct ($new name, $new age, $new salary) {
        $this -> salary = $new salary;
       parent:: construct($new name, $new age);
     function update salary($new salary)
       $this -> salary = $new salary;
     $emp = new Employee('Dave Underwood', 25, 25000);
?>
```

# Inheritance (cont.)

- The constructor of the parent <u>isn't called</u> unless the child explicitly references it (as in this previous case).
- You could "hard-code" the call to the parent constructor using the function call "Person::\_\_construct(\$new\_name, \$new\_age);"
- You can use the "self" keyword to ensure that a method is called on the current class (if a method might be subclassed), in this style self::method();
- To check if an object is of a particular class, you can use the instanceof operator.

#### More on classes

- You can also define interfaces (for which any class that uses that interface must provide implementations of certain methods), and you can define abstract classes or methods (that must be overridden by its children).
- The keyword "final" can be used to denote a method that cannot be overridden by its children.

```
class Person {
   public $name;

   final function get_name() {
     return $this -> name;
   }
}
```

#### Session

#### PHP sessions

- By default, HTML and web servers don't keep track of information entered on a page when the client's browser opens another page.
- A session is a way to store information (in variables) to be used across multiple pages.
- Unlike a cookie, the information is not stored on the users computer.
- Sessions only store information temporarily

## PHP sessions (cont.)

• To start a session, use the function session\_start() at the beginning of your PHP script before you store or access any data. For the session to work properly, this function needs to execute before any other header calls or other output is sent to the browser.

```
<?php
session start();
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"</pre>
          "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
<html xmlns="http://www.w3.org/1999/xhtml" xml:lang="en" lang="en">
<head>
<title>Session example</title>
</head>
<body>
<?php
include once ('object.php'); // Includes definition of the Person class
$ SESSION['hello'] = 'Hello world';
echo $ SESSION['hello'] . "<br/>\n";
$ SESSION['one'] = 'one';
$ SESSION['two'] = 'two';
\frac{1}{2} = new Person("Russ", 36, 2892700);
$ SESSION['name'] = $me->get name();
echo "Testing " . $ SESSION['one'] .", " . $ SESSION['two'] . ", " . $me->get number() . " . . . <br/>\n";
                                                                                    view the output page
</body></html>
```

#### Using session variables

Once a session variable has been defined, you can access it from other pages.

```
<?php
session start();
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"</pre>
          "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
<html xmlns="http://www.w3.org/1999/xhtml" xml:lang="en" lang="en">
<head>
<title>Session example 2</title>
</head>
<body>
<?php
echo "Welcome to a new page ". $ SESSION['name'] "!<br/>\n";
echo "Hope you enjoy your stay! <br/>";
?>
Back to regular HTML text...
</body>
</html>
```

view the output page

#### More on session variables

- You need to include a call to the session\_start() function for each page on which you want to access the session variables.
- A session will end once you quit the browser (unless you've set appropriate cookies that will persist), or you can call the session\_destroy() function.
- The function session\_unset() removes all session variables. If you want to remove one variable, use the unset(\$var) function call.
- The default timeout for session is 24 minutes. It's possible to change this timeout.

## Deleting all session variables

```
<?php
session start();
?>
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"</pre>
          "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
<html xmlns="http://www.w3.org/1999/xhtml" xml:lang="en" lang="en">
<head>
<title>Session example 3</title>
</head>
<body>
<?php
echo "Deleting all session variables using session unset(); <br/>\n";
session unset();
echo "Now the session variables are gone. <br/> \n";
if (isset($ SESSION['name']))
     echo $ SESSION['name'] . "<br/>\n"; }
else
      echo "Session variable is not here."; }
?>
</body>
```

</html>

view the output page

# PHP and MySQL

#### Putting Content into Your Database with PHP5+

Connect to the database server and login

```
mysqli connect("servername", "username", "password", "database");
```

Send SQL queries to the server to add, delete, and modify data

```
mysqli query("query");
```

Close the connection to the database server (to ensure the information is stored properly)

```
mysqli close();
```

### Student Database: data\_in.php

```
<ht.ml>
<head>
<title>Putting Data in the DB</title>
</head>
<body>
<?php
/*insert students into DB*/
if(isset($ POST["submit"]))
  $conn = mysqli connect("mysql", "martin", "martin", "martin");
  if (!$conn) {
      die("Connection failed: " . mysqli connect error());
  $date=date("Y-m-d"); /* Get the current date in the right SQL format */
  $sql="INSERT INTO students VALUES(NULL,'" . $ POST["f name"] . "','" . $ POST["l name"] . "'," .
    $ POST["student id"] . ",'" . $ POST["email"] . "','" . $date . "'," . $ POST["gr"] . ")"; /*
    construct the query */
  mysqli query($conn, $sql); /* execute the query */
  mysqli close();
  echo"<h3>Thank you. The data has been entered.</h3> \n";
  echo'<a href="data in.php">Back to registration</a>' . "\n";
  echo'<a href="data out.php">View the student lists</a>' ."\n";
```

## Student Database: data\_in.php

```
else {
5>
<h3>Enter your items into the database</h3>
<form action="data in.php" method="post">
First Name: <input type="text" name="f name" /> <br/>
Last Name: <input type="text" name="l name" /> <br/>
ID: <input type="text" name="student id" /> <br/>
email: <input type="text" name="email" /> <br/>
Group: <select name="gr">
      <option value ="1">1</option>
      <option value ="2">2</option>
      <option value ="3">3</option>
</select><br/><br/>
<input type="submit" name="submit" /> <input type="reset" />
</form>
<?php
        /* end of "else" block */
?>
</body>
</html>
```

#### **Getting Content out**

Send an SQL query to the server to select data from the database into an array

```
$result=mysqli_query($conn, $query);
while ($row = mysqli_ fetch_assoc($result)) {
   //hiển thị dữ liệu
echo "Id: " . $row["id"] . " - Name: " . $row["name"] . " <br/>";
}
```

### Student Database: data\_out.php

```
<html>
<head>
<title>Getting Data out of the DB</title>
</head>
<body>
<h1> Student Database </h1>
 Order the full list of students by
<a href="data out.php?order=date">date</a>,
<href="data out.php?order=student id">id</a>, or
by <a href="data out.php?order=1 name">surname</a>.
<q>
<form action="data out.php" method="post">
Or only see the list of students in group
<select name="gr">
  <option value ="1">1</option>
 <option value ="2">2</option>
  <option value ="3">3</option>
</select>
\langle br/ \rangle
<input type="submit" name="submit" />
</form>
```

## Student Database: data\_out.php

```
<?php
$db = mysqli connect("mysql", "martin", "martin");
switch($ GET["order"]){
case 'date': $sql = "SELECT * FROM students ORDER BY date"; break;
case 'student id': $sql = "SELECT * FROM students ORDER BY student id"; break;
case 'l name': $sql = "SELECT * FROM students ORDER BY l name"; break;
default: $sql = "SELECT * FROM students"; break;
if(isset($ POST["submit"])){
  $sql = "SELECT * FROM students WHERE gr=" . $ POST["gr"];
$result=mysqli query($db, $sql); /* execute the query */
while($row=mysql fetch assoc($result)){
  echo "<h4> Name: " . $row["l_name"] . ', ' . $row["f_name"] . "</h4> \n";
  echo "<h5> ID: " . $row["student id"] . "<br/> Email: " . $row["email"] . "<br/> Group: "
   . $row["gr"] . "<br/> Posted: " . $row["date"] . "</h5> \n";
mysqli close();
?>
</body>
</html>
```

#### More on PHP and SQL

To increase security of your PHP/SQL setup (and to make it easier to change the database you use), it's recommended that you build an "include" file that will have the information you use to connect to the database.

```
<?php
/* Save this as db_login.php (or whatever you like) and include it
in your php script. */

// Here's the information to connect to the database.
$db_host = 'mysql';
$db_database='martin';
$db_username='martin';
$db_password='xxxxx';
?>
```

If someone tries to view this file through their browser, the PHP interpreter will process it and return a blank page to the user (there's no HTML in the file).

#### Connecting to the database

Now you can build your PHP script as follows (using the commands that we discussed previously):

<u>Note:</u> The function 'htmlspecialchars()' converts special characters in a string into their HTML escape sequences (like '&' into '&amp;' and so forth).

This can also be used to increase the security of your code by and help thwart attacks on your database by passing it information that your client has submitted <u>before</u> trying to insert it in your database.

### MySQL queries inside of PHP

Your mySQL queries from a PHP script are the same as they are as when you're using the mySQL program from the command line with one difference... the queries do not have a semi-colon at the end.
